Overview

- **Population ecology** is the study of populations in relation to **environment**, including environmental influences on **density** and **distribution**, age structure, and **population size**.
- A **population** is a group of individuals of a single species living in the same general area.

Dynamic biological processes influence population density, dispersion, and demographics

- **Density** is the number of **individuals per unit area** or volume.
- **Dispersion** is the **pattern of spacing** among individuals within the boundaries of the population.
- **Density is the result of an interplay between processes that add individuals to a population and those that remove individuals (population dynamics).**

Population dynamics

Patterns of dispersion within a population's geographic range

(a) **Clumped**

In a **clumped** dispersion, individuals aggregate in **patches**. A clumped dispersion may be influenced by **resource availability** and behavior.

(b) **Uniform**

A **uniform** dispersion is one in which individuals are evenly distributed. It may be influenced by social interactions such as **territoriality**.

(c) **Random**

In a **random** dispersion, the position of each individual is independent of other individuals. It occurs in the **absence of strong attractions or repulsions**.

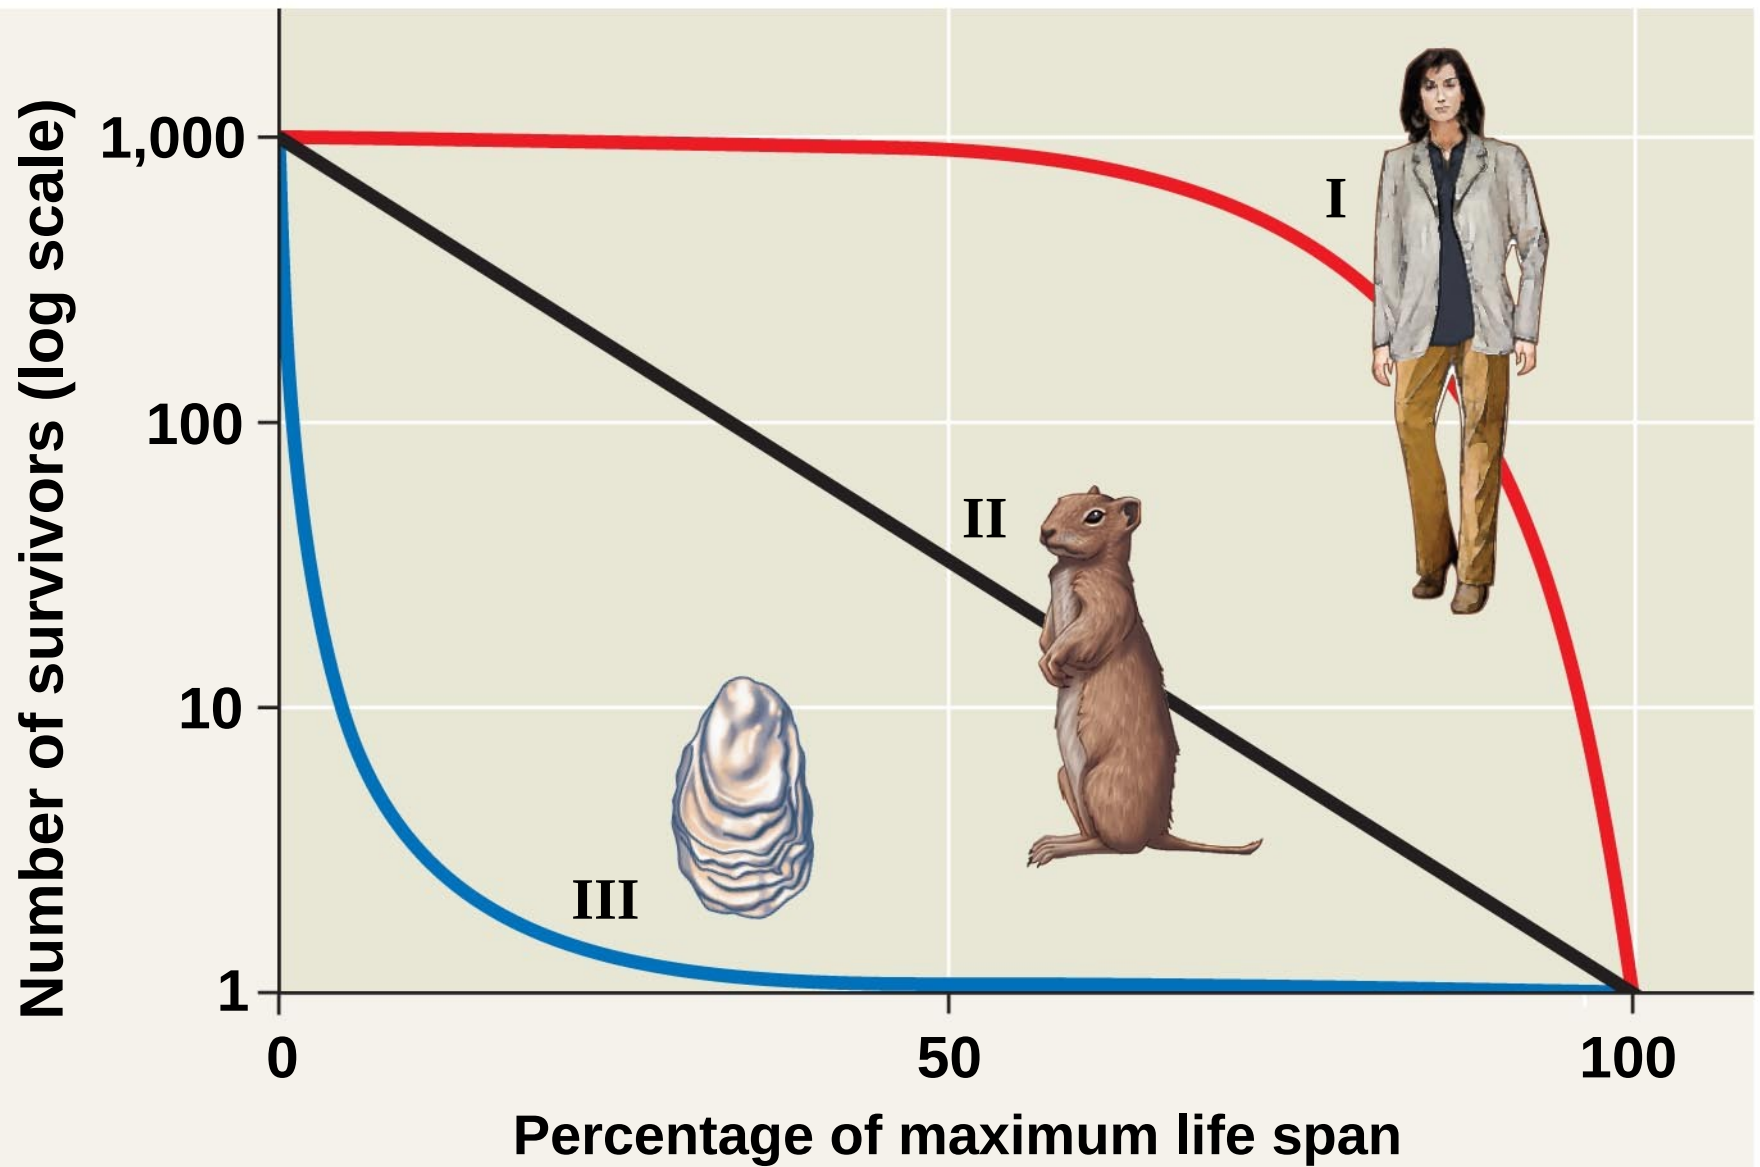

Demographics

- **Demography** is the study of the **vital statistics** of a population and how they change over time.

Death rates and birth rates are of particular interest to demographers (**survivorship curve**).

-
- **Survivorship curves** can be classified into three general types:
 - **Type I: low death rates during early and middle life**, then an increase among older age groups
 - **Type II: the death rate is constant over the organism's life span**
 - **Type III: high death rates for the young**, then a slower death rate for survivors

Survivorship Curves

The exponential model describes population growth in an idealized, unlimited environment

- It is **useful to study population growth** in an **idealized situation**.
- Idealized situations help us understand the **capability of a species to increase** and the conditions that may facilitate this growth.

-
- **Zero population growth** occurs when the **birth rate equals the death rate**.
 - Most ecologists use differential calculus to express population growth as growth rate at a particular instant in time:

$$\frac{\Delta N}{\Delta t} = rN$$

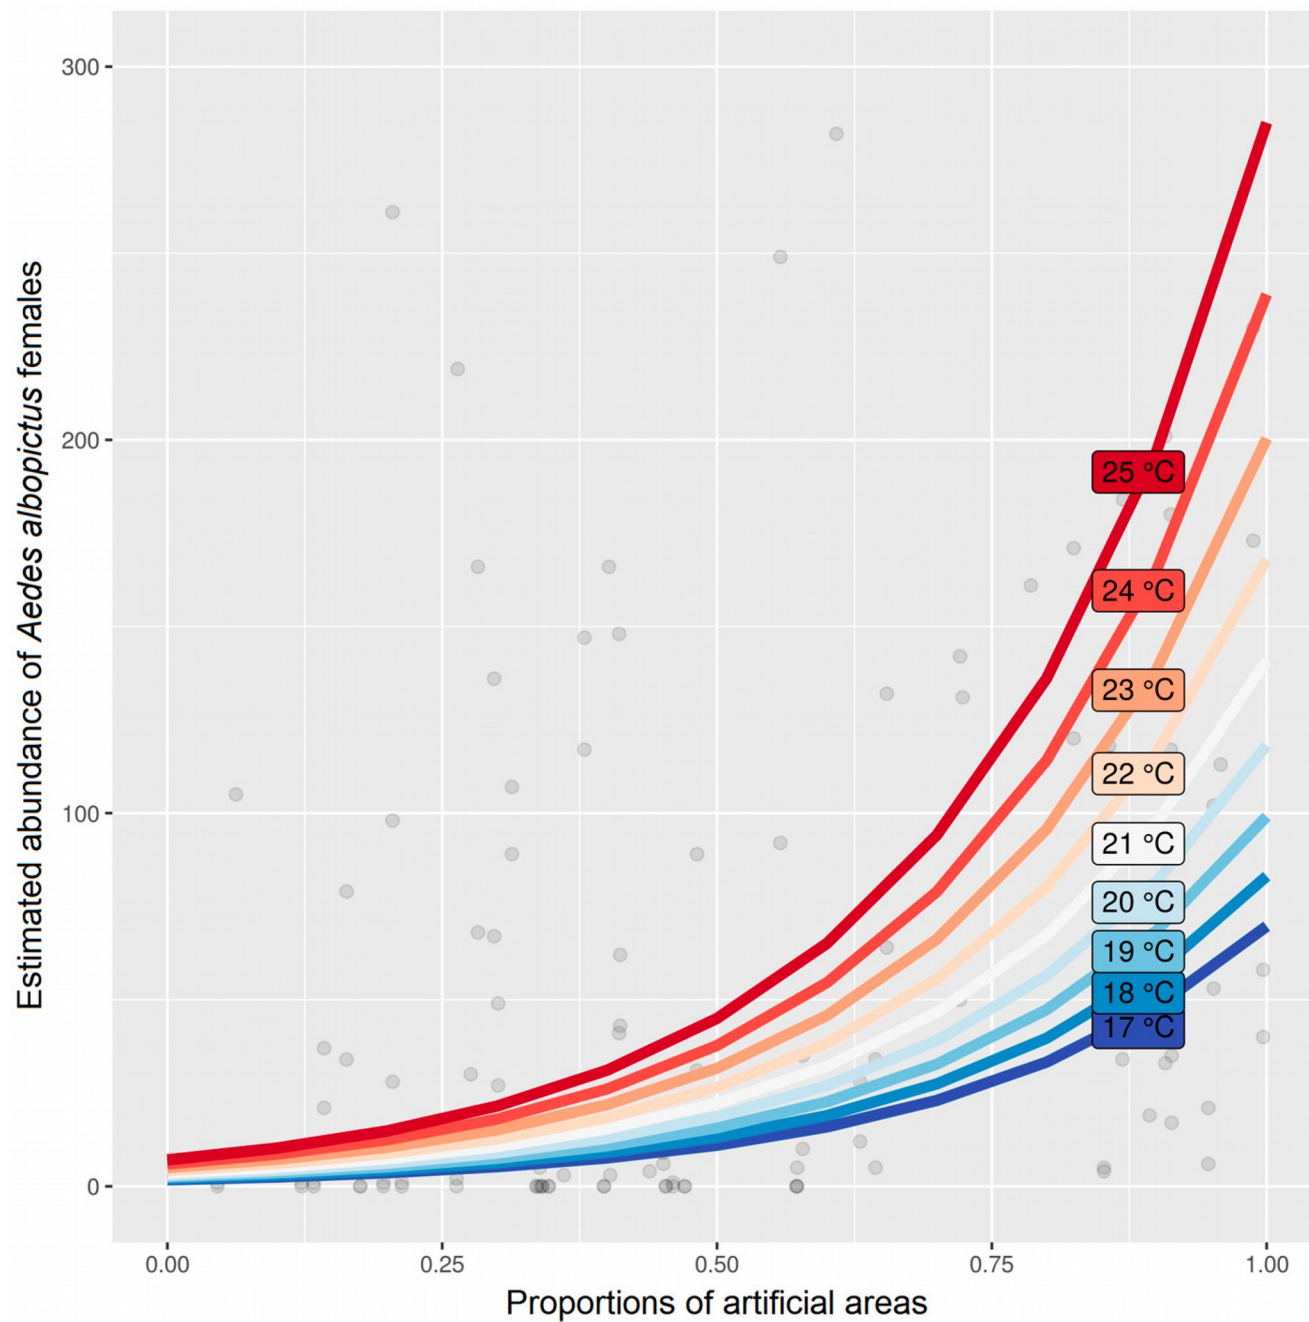

where N = population size, t = time, and r = per capita rate of increase = birth – death

Exponential Growth

- **Exponential population growth** is population increase under **idealized conditions**.
- Under these conditions, the rate of reproduction is at its maximum, called the intrinsic rate of increase.
- Exponential population growth results in a **J-shaped curve**
- Exponential Growth is not sustainable.

Exponential Growth Model

The logistic model describes how a population grows more slowly as it nears its carrying capacity

- Exponential growth cannot be sustained for long in any population. A more realistic population model limits growth by incorporating carrying capacity.
- **Carrying capacity (K)** is the maximum population size the environment can support.
- In the **logistic population growth** model, the *rate of increase declines as carrying capacity is reached*.
- The *logistic model* of population growth produces a **sigmoid (S-shaped) curve**.

Logistic Growth model

The Logistic Model and Real Populations

- **The growth of laboratory populations of paramecia fits an S-shaped curve.**
- These organisms are grown in a constant environment lacking predators and competitors.
- **Some populations overshoot K before settling down to a relatively stable density.**

The growth of laboratory populations fits an **S-shaped curve** which hovers around the **Carrying Capacity** of the area.

(b) A *Daphnia* population in the lab

The Logistic Model and r- and K- species

- **r-species** = select for life traits that **maximize reproduction; e.g. new niches available**
- **K-species** = select for life traits that are **related to higher competition**

WHY r- and K?

Logistic Growth model

Immigration, Emigration, and Metapopulations

- **Metapopulations** are groups of populations linked by **immigration and emigration**.
- High levels of immigration combined with **higher survival can result in greater stability in populations**.

Estimates of Earth's Carrying Capacity

- **How many humans** can the biosphere support?
- The carrying capacity of Earth for humans is uncertain.
- **The average estimate is 10–15 billion.**

Limits on Human Population Size

- The **ecological footprint** concept summarizes the aggregate land and water area needed to sustain the people of a nation.
- It is one measure of how close we are to the carrying capacity of Earth.
- Countries vary greatly in footprint size and available ecological capacity.
- *Our carrying capacity could potentially be limited by food, space, nonrenewable resources, or buildup of wastes.*
